Abstract: This work presents new results about the reliable identification of the main transition velocity  $U_{\text{trans-1}}$  in different bubble columns (0.1 – 0.46 m in inner diameter) equipped with several perforated plate gas distributors. Two different gas-liquid systems (air-water and air-therminol LT) have been used. The most important finding in this work is that  $U_{\text{trans-1}}$  (end of the homogeneous regime) occurs at  $0.04 \text{ m}\cdot\text{s}^{-1}$  irrespective of the operating conditions studied. For the  $U_{\text{trans-1}}$  identification, the following parameters have been used: Kolmogorov and reconstruction entropies, degree of randomness and information entropy.
