Abstract: The biodegradation of phenol by *Stenotrophomonas maltophilia* KB2 strain in a batch reactor was studied. Microbial growth tests in the presence of phenol as the sole carbon and energy source were conducted for different initial concentrations of the degraded compound changed in the range 25-500 g•m⁻³. Haldane's growth kinetic model was found to be the best to fit the experimental data so constants of the kinetic equation as well as yield coefficient were estimated.
